Methodology of
Annual Population Estimation

## At The Department of Statistics

The Population and Housing Censuses conducted by the Department of Statistics are the prime and accurate source of population data on size and geographic and administrative distribution. Population censuses are the basis for estimating the annual number of population for the periods between censuses. The exponential equations are usually used, where dynamics of the population are almost stable and there are no sources of lead to sudden population changes. In this case, the annual rate of population growth for the period between two consecutive censuses is almost constant and estimated with high level of precision.

The annual rate of population growth between censuses is estimated using the formula:

$$
\mathrm{r}=1 / \mathrm{t} \operatorname{Ln}\left(\mathrm{P}_{\mathrm{t}} / \mathrm{P}_{0}\right)
$$

$r=$ annual rate of population growth
$\mathrm{P}_{\mathrm{t}}=$ Population size of the following Census
$\mathrm{P}_{0}=$ Population size of the previous census
$\mathrm{t}=$ period (in years) between the two censuses

Using the estimated annual rate of population growth (r) from the previous step, the annual population size is estimated using the following formula:

$$
\mathrm{P}_{1}=\mathrm{P}_{0} * \mathrm{e}^{\mathrm{rt}}
$$

Where,
$\mathrm{r}=$ annual rate of population growth
$\mathrm{P}_{1}=$ Population size of the consecutive year
$\mathrm{P}_{0}=$ Population size of the previous year
$\mathrm{t}=1$
Using this formula, the population size can be estimated for each year as long as the population dynamics are somewhat stable.

In cases where emerging population changes, take place for any reason including forced migration driven by insecurity due to armed conflicts or other reasons such as natural disaster leading to great losses of population groups, an additional dimension is considered in order to take such changes into account. In this case the growthbalance equation is used:
$\mathrm{P}_{1}=\mathrm{P}_{0}+\mathrm{B}-\mathrm{D}+\mathrm{IM}-\mathrm{EM}$
$\mathrm{P}_{1}=$ Population size of the consecutive year
$\mathrm{P}_{0}=$ Population size of the previous year
$\mathrm{B}=$ number of births during the year
$\mathrm{D}=$ Number of deaths during the year
$\mathrm{IM}=$ Immigration to the country (arrivals)
$\mathrm{EM}=$ Emigration from the coutry (departures)

Starting from 1952, where the first census was conducted, till 2015, the growth-balance equation was used to complement the exponential equation utilizing data from administrative records that provide aggregate data on population mobility. These data are generated by the Department of Boarder and Residence, the Department of Civil Status and Passports, Ministry of Labor and other institutions, in addition to specialized studies. Such data were used for population
estimation for years affected by emerging changes including 1967 and migration from the West Bank, 1990 and 1991 to take account of return migrants from the Gulf due to Iraqi occupation of Kuwait, the post 2003 migration of Iraqis to Jordan and finally the 2011and after which witnessed migration of Syrians due to armed conflict. The total number of Syrians accounted for in the 2015 Population census amounted to about 1.3 million, with almost half as refugees.

For the post 2015 census, estimation of the population size in Jordan will be conducted using a combination of the exponential method as well as the growth balance equation that builds on the data generated from the administrative records.

Population Trend of Jordan, 1961-2015

| Year | Population (000) | Annual Growth (\%) |
| :---: | :---: | :---: |
| ${ }^{(1)} 1961$ | 900.8 | - |
| 1962 | 931.0 | 3.30 |
| 1963 | 962.2 | 3.30 |
